Slides merged from two different talks/lectures of David Silver*

Large-Scale Reinforcement Learning

Reinforcement learning can be used to solve *large* problems, e.g.

- Backgammon: 10^{20} states
- Computer Go: 10^{170} states
- Helicopter: continuous state space

Value Function Approximation

- So far we have represented value function by a *lookup table*
 - Every state s has an entry $V(s)$
 - Or every state-action pair s, a has an entry $Q(s, a)$
- Problem with large MDPs:
 - There are too many states and/or actions to store in memory
 - It is too slow to learn the value of each state individually
- Solution for large MDPs:
 - Estimate value function with *function approximation*

$$\hat{v}(s, \mathbf{w}) \approx v_{\pi}(s)$$

or $\hat{q}(s, a, \mathbf{w}) \approx q_{\pi}(s, a)$

- *Generalise* from seen states to unseen states
- *Update* parameter \mathbf{w} using MC or TD learning

Types of Value Function Approximation

Which Function Approximator?

There are many function approximators, e.g.

- Linear combinations of features
- Neural network
- Decision tree
- Nearest neighbour
- Fourier / wavelet bases
- ...

Which Function Approximator?

We consider **differentiable** function approximators, e.g.

- **Linear combinations of features**
- **Neural network**
- Decision tree
- Nearest neighbour
- Fourier / wavelet bases
- ...

Furthermore, we require a training method that is suitable for **non-stationary**, **non-iid** data

Gradient Descent

- Let $J(\mathbf{w})$ be a differentiable function of parameter vector \mathbf{w}
- Define the *gradient* of $J(\mathbf{w})$ to be

$$\nabla_{\mathbf{w}} J(\mathbf{w}) = \begin{pmatrix} \frac{\partial J(\mathbf{w})}{\partial w_1} \\ \vdots \\ \frac{\partial J(\mathbf{w})}{\partial w_n} \end{pmatrix}$$

- To find a local minimum of $J(\mathbf{w})$
- Adjust \mathbf{w} in direction of -ve gradient

$$\Delta \mathbf{w} = -\frac{1}{2} \alpha \nabla_{\mathbf{w}} J(\mathbf{w})$$

where α is a step-size parameter

Action-Value Function Approximation

- Approximate the action-value function

$$\hat{q}(S, A, \mathbf{w}) \approx q_\pi(S, A)$$

- Minimise mean-squared error between approximate action-value fn $\hat{q}(S, A, \mathbf{w})$ and true action-value fn $q_\pi(S, A)$

$$J(\mathbf{w}) = \mathbb{E}_\pi [(q_\pi(S, A) - \hat{q}(S, A, \mathbf{w}))^2]$$

- Use stochastic gradient descent to find a local minimum

$$-\frac{1}{2} \nabla_{\mathbf{w}} J(\mathbf{w}) = (q_\pi(S, A) - \hat{q}(S, A, \mathbf{w})) \nabla_{\mathbf{w}} \hat{q}(S, A, \mathbf{w})$$

$$\Delta \mathbf{w} = \alpha (q_\pi(S, A) - \hat{q}(S, A, \mathbf{w})) \nabla_{\mathbf{w}} \hat{q}(S, A, \mathbf{w})$$

Linear Action-Value Function Approximation

- Represent state *and* action by a *feature vector*

$$\mathbf{x}(S, A) = \begin{pmatrix} \mathbf{x}_1(S, A) \\ \vdots \\ \mathbf{x}_n(S, A) \end{pmatrix}$$

- Represent action-value fn by linear combination of features

$$\hat{q}(S, A, \mathbf{w}) = \mathbf{x}(S, A)^\top \mathbf{w} = \sum_{j=1}^n \mathbf{x}_j(S, A) \mathbf{w}_j$$

- Stochastic gradient descent update

$$\nabla_{\mathbf{w}} \hat{q}(S, A, \mathbf{w}) = \mathbf{x}(S, A)$$

$$\Delta \mathbf{w} = \alpha (q_\pi(S, A) - \hat{q}(S, A, \mathbf{w})) \mathbf{x}(S, A)$$

Batch Reinforcement Learning

- Gradient descent is simple and appealing
- But it is *not* sample efficient
- Batch methods seek to find the best fitting value function
- Given the agent's experience ("training data")

Least Squares Prediction

- Given value function approximation $\hat{v}(s, \mathbf{w}) \approx v_\pi(s)$
- And *experience* \mathcal{D} consisting of $\langle \text{state}, \text{value} \rangle$ pairs

$$\mathcal{D} = \{ \langle s_1, v_1^\pi \rangle, \langle s_2, v_2^\pi \rangle, \dots, \langle s_T, v_T^\pi \rangle \}$$

- Which parameters \mathbf{w} give the *best fitting* value fn $\hat{v}(s, \mathbf{w})$?
- **Least squares** algorithms find parameter vector \mathbf{w} minimising sum-squared error between $\hat{v}(s_t, \mathbf{w})$ and target values v_t^π ,

$$\begin{aligned} LS(\mathbf{w}) &= \sum_{t=1}^T (v_t^\pi - \hat{v}(s_t, \mathbf{w}))^2 \\ &= \mathbb{E}_{\mathcal{D}} [(v^\pi - \hat{v}(s, \mathbf{w}))^2] \end{aligned}$$

Stochastic Gradient Descent with Experience Replay

Given experience consisting of $\langle \text{state}, \text{value} \rangle$ pairs

$$\mathcal{D} = \{ \langle s_1, v_1^\pi \rangle, \langle s_2, v_2^\pi \rangle, \dots, \langle s_T, v_T^\pi \rangle \}$$

Repeat:

- 1 Sample state, value from experience

$$\langle s, v^\pi \rangle \sim \mathcal{D}$$

- 2 Apply stochastic gradient descent update

$$\Delta \mathbf{w} = \alpha (v^\pi - \hat{v}(s, \mathbf{w})) \nabla_{\mathbf{w}} \hat{v}(s, \mathbf{w})$$

Stochastic Gradient Descent with Experience Replay

Given experience consisting of $\langle \text{state}, \text{value} \rangle$ pairs

$$\mathcal{D} = \{ \langle s_1, v_1^\pi \rangle, \langle s_2, v_2^\pi \rangle, \dots, \langle s_T, v_T^\pi \rangle \}$$

Repeat:

- 1 Sample state, value from experience

$$\langle s, v^\pi \rangle \sim \mathcal{D}$$

- 2 Apply stochastic gradient descent update

$$\Delta \mathbf{w} = \alpha (v^\pi - \hat{v}(s, \mathbf{w})) \nabla_{\mathbf{w}} \hat{v}(s, \mathbf{w})$$

Converges to least squares solution

$$\mathbf{w}^\pi = \underset{\mathbf{w}}{\operatorname{argmin}} LS(\mathbf{w})$$

Deep Reinforcement Learning

- ▶ Can we apply deep learning to RL?
- ▶ Use deep network to represent value function / policy / model
- ▶ Optimise value function / policy /model **end-to-end**
- ▶ Using stochastic gradient descent

Bellman Equation

- ▶ Value function can be unrolled recursively

$$\begin{aligned} Q^\pi(s, a) &= \mathbb{E} [r_{t+1} + \gamma r_{t+2} + \gamma^2 r_{t+3} + \dots \mid s, a] \\ &= \mathbb{E}_{s'} [r + \gamma Q^\pi(s', a') \mid s, a] \end{aligned}$$

- ▶ Optimal value function $Q^*(s, a)$ can be unrolled recursively

$$Q^*(s, a) = \mathbb{E}_{s'} \left[r + \gamma \max_{a'} Q^*(s', a') \mid s, a \right]$$

- ▶ Value iteration algorithms solve the Bellman equation

$$Q_{i+1}(s, a) = \mathbb{E}_{s'} \left[r + \gamma \max_{a'} Q_i(s', a') \mid s, a \right]$$

Experience Replay in Deep Q-Networks (DQN)

DQN uses **experience replay** and **fixed Q-targets**

- Take action a_t according to ϵ -greedy policy
- Store transition $(s_t, a_t, r_{t+1}, s_{t+1})$ in replay memory \mathcal{D}
- Sample random mini-batch of transitions (s, a, r, s') from \mathcal{D}
- Compute Q-learning targets w.r.t. old, fixed parameters w^-
- Optimise MSE between Q-network and Q-learning targets

$$\mathcal{L}_i(w_i) = \mathbb{E}_{s,a,r,s' \sim \mathcal{D}_i} \left[\left(r + \gamma \max_{a'} Q(s', a'; w_i^-) - Q(s, a; w_i) \right)^2 \right]$$

- Using variant of stochastic gradient descent

Deep Q-Learning

- Represent value function by deep **Q-network** with weights w

$$Q(s, a, w) \approx Q^\pi(s, a)$$

- Define objective function by mean-squared error in Q-values

$$\mathcal{L}(w) = \mathbb{E} \left[\left(\underbrace{r + \gamma \max_{a'} Q(s', a', w)}_{\text{target}} - Q(s, a, w) \right)^2 \right]$$

- Leading to the following **Q-learning** gradient

$$\frac{\partial \mathcal{L}(w)}{\partial w} = \mathbb{E} \left[\left(r + \gamma \max_{a'} Q(s', a', w) - Q(s, a, w) \right) \frac{\partial Q(s, a, w)}{\partial w} \right]$$

- Optimise objective end-to-end by SGD, using $\frac{\partial \mathcal{L}(w)}{\partial w}$

Stability Issues with Deep RL

Naive Q-learning **oscillates** or **diverges** with neural nets

1. Data is sequential
 - ▶ Successive samples are correlated, non-iid
2. Policy changes rapidly with slight changes to Q-values
 - ▶ Policy may oscillate
 - ▶ Distribution of data can swing from one extreme to another
3. Scale of rewards and Q-values is unknown
 - ▶ Naive Q-learning gradients can be large
unstable when backpropagated

Deep Q-Networks

DQN provides a stable solution to deep value-based RL

1. Use **experience replay**
 - ▶ Break correlations in data, bring us back to iid setting
 - ▶ Learn from all past policies
2. Freeze **target Q-network**
 - ▶ Avoid oscillations
 - ▶ Break correlations between Q-network and target
3. **Clip** rewards or **normalize** network adaptively to sensible range
 - ▶ Robust gradients

Stable Deep RL (1): Experience Replay

To remove correlations, build data-set from agent's own experience

- ▶ Take action a_t according to ϵ -greedy policy
- ▶ Store transition $(s_t, a_t, r_{t+1}, s_{t+1})$ in replay memory \mathcal{D}
- ▶ Sample random mini-batch of transitions (s, a, r, s') from \mathcal{D}
- ▶ Optimise MSE between Q-network and Q-learning targets, e.g.

$$\mathcal{L}(w) = \mathbb{E}_{s, a, r, s' \sim \mathcal{D}} \left[\left(r + \gamma \max_{a'} Q(s', a', w) - Q(s, a, w) \right)^2 \right]$$

Stable Deep RL (2): Fixed Target Q-Network

To avoid oscillations, fix parameters used in Q-learning target

- Compute Q-learning targets w.r.t. old, fixed parameters w^-

$$r + \gamma \max_{a'} Q(s', a', w^-)$$

- Optimise MSE between Q-network and Q-learning targets

$$\mathcal{L}(w) = \mathbb{E}_{s,a,r,s' \sim \mathcal{D}} \left[\left(r + \gamma \max_{a'} Q(s', a', w^-) - Q(s, a, w) \right)^2 \right]$$

- Periodically update fixed parameters $w^- \leftarrow w$

Stable Deep RL (3): Reward/Value Range

- ▶ DQN clips the rewards to $[-1, +1]$
- ▶ This prevents Q-values from becoming too large
- ▶ Ensures gradients are well-conditioned
- ▶ Can't tell difference between small and large rewards

Reinforcement Learning in Atari

DQN in Atari

- ▶ End-to-end learning of values $Q(s, a)$ from pixels s
- ▶ Input state s is stack of raw pixels from last 4 frames
- ▶ Output is $Q(s, a)$ for 18 joystick/button positions
- ▶ Reward is change in score for that step

Network architecture and hyperparameters fixed across all games
[Mnih et al.]

DQN Results in Atari

How much does DQN help?

DQN

	Q-learning	Q-learning + Target Q	Q-learning + Replay	Q-learning + Replay + Target Q
Breakout	3	10	241	317
Enduro	29	142	831	1006
River Raid	1453	2868	4103	7447
Seaquest	276	1003	823	2894
Space Invaders	302	373	826	1089

Conclusion

- ▶ RL provides a general-purpose framework for AI
- ▶ RL problems can be solved by end-to-end deep learning
- ▶ A single agent can now solve many challenging tasks
- ▶ Reinforcement learning + deep learning = AI

Questions?

“The only stupid question is the one you never ask” -*Rich Sutton*
